

Assignment II

Anna Prince

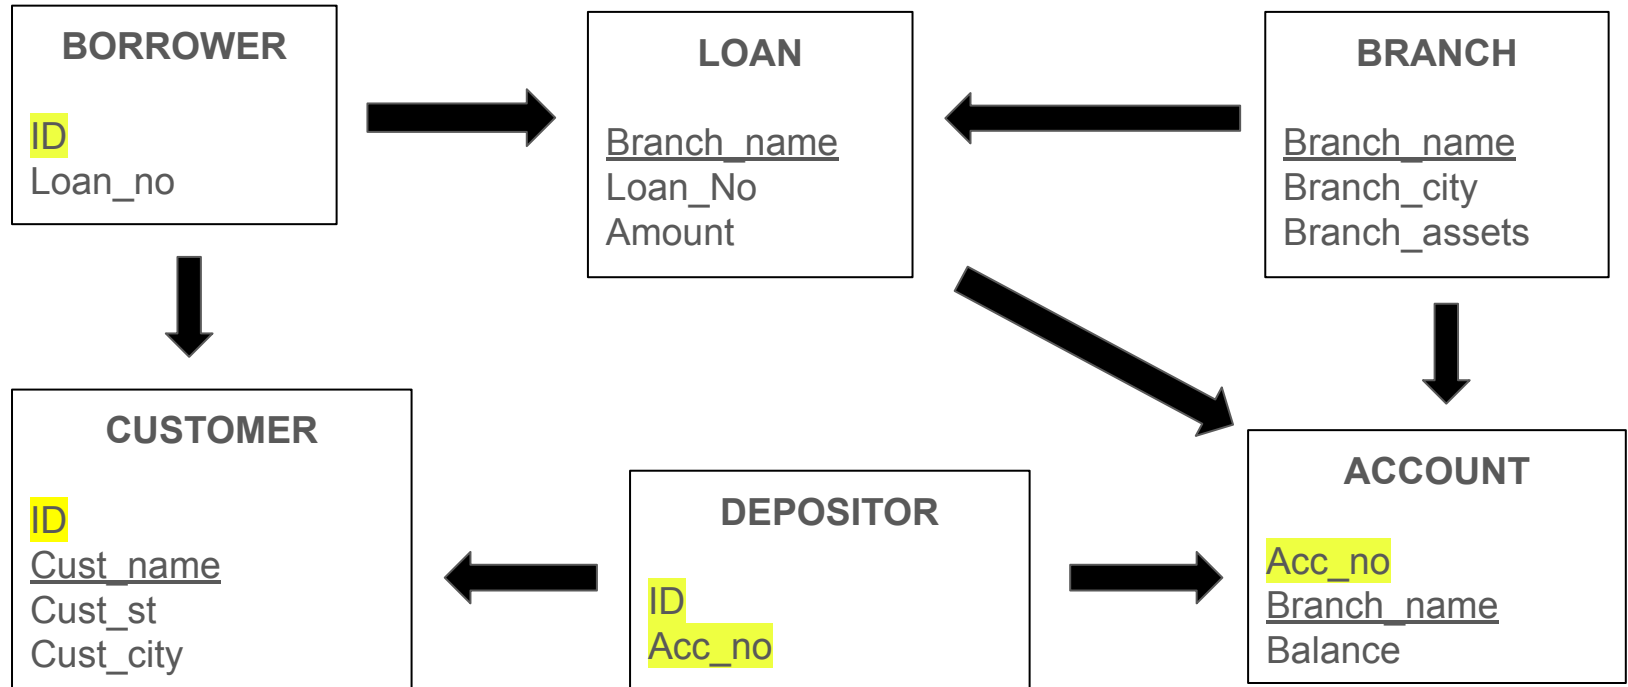

Q1: Schema, Relation, Instance

Relation schema: design for how things should relate to one another, i.e. attributes and their respective domains.

Relation: the table in the database, i.e. the data itself as organized by the schema

Instance: specific instance of a relation, i.e. a “snapshot” of the data at a given point in time

Q2: Bank Database Schema Diagram

Q3: AI Applications

1. AI could identify information that isn't identical, but is redundant. This method could apply to data entry errors or misspellings (“account_no” versus “account_number”), or logic-type errors (e.g. attributes “income” and “salary” repackaged the same information).
2. ChatBots could refine queries based on user input, or write SQL based on written descriptions. This would make it accessible to non-experts and reduce the need for training them.
